

# Motivation

The heatwaves have increased in duration, frequency and intensity over the years along with the global climate change, and will continue to do so!

The individual can be affected by the heat in the **short** and **long** term:

<b>SHORT</b>	Nauseous	<b>LONG</b>	Dehydration
	Exhausted		can injure kidneys
	Heat stroke		

The climate within the city differs from that in its outskirts, leading to a temperature gradient → Urban Heat Island (UHI)

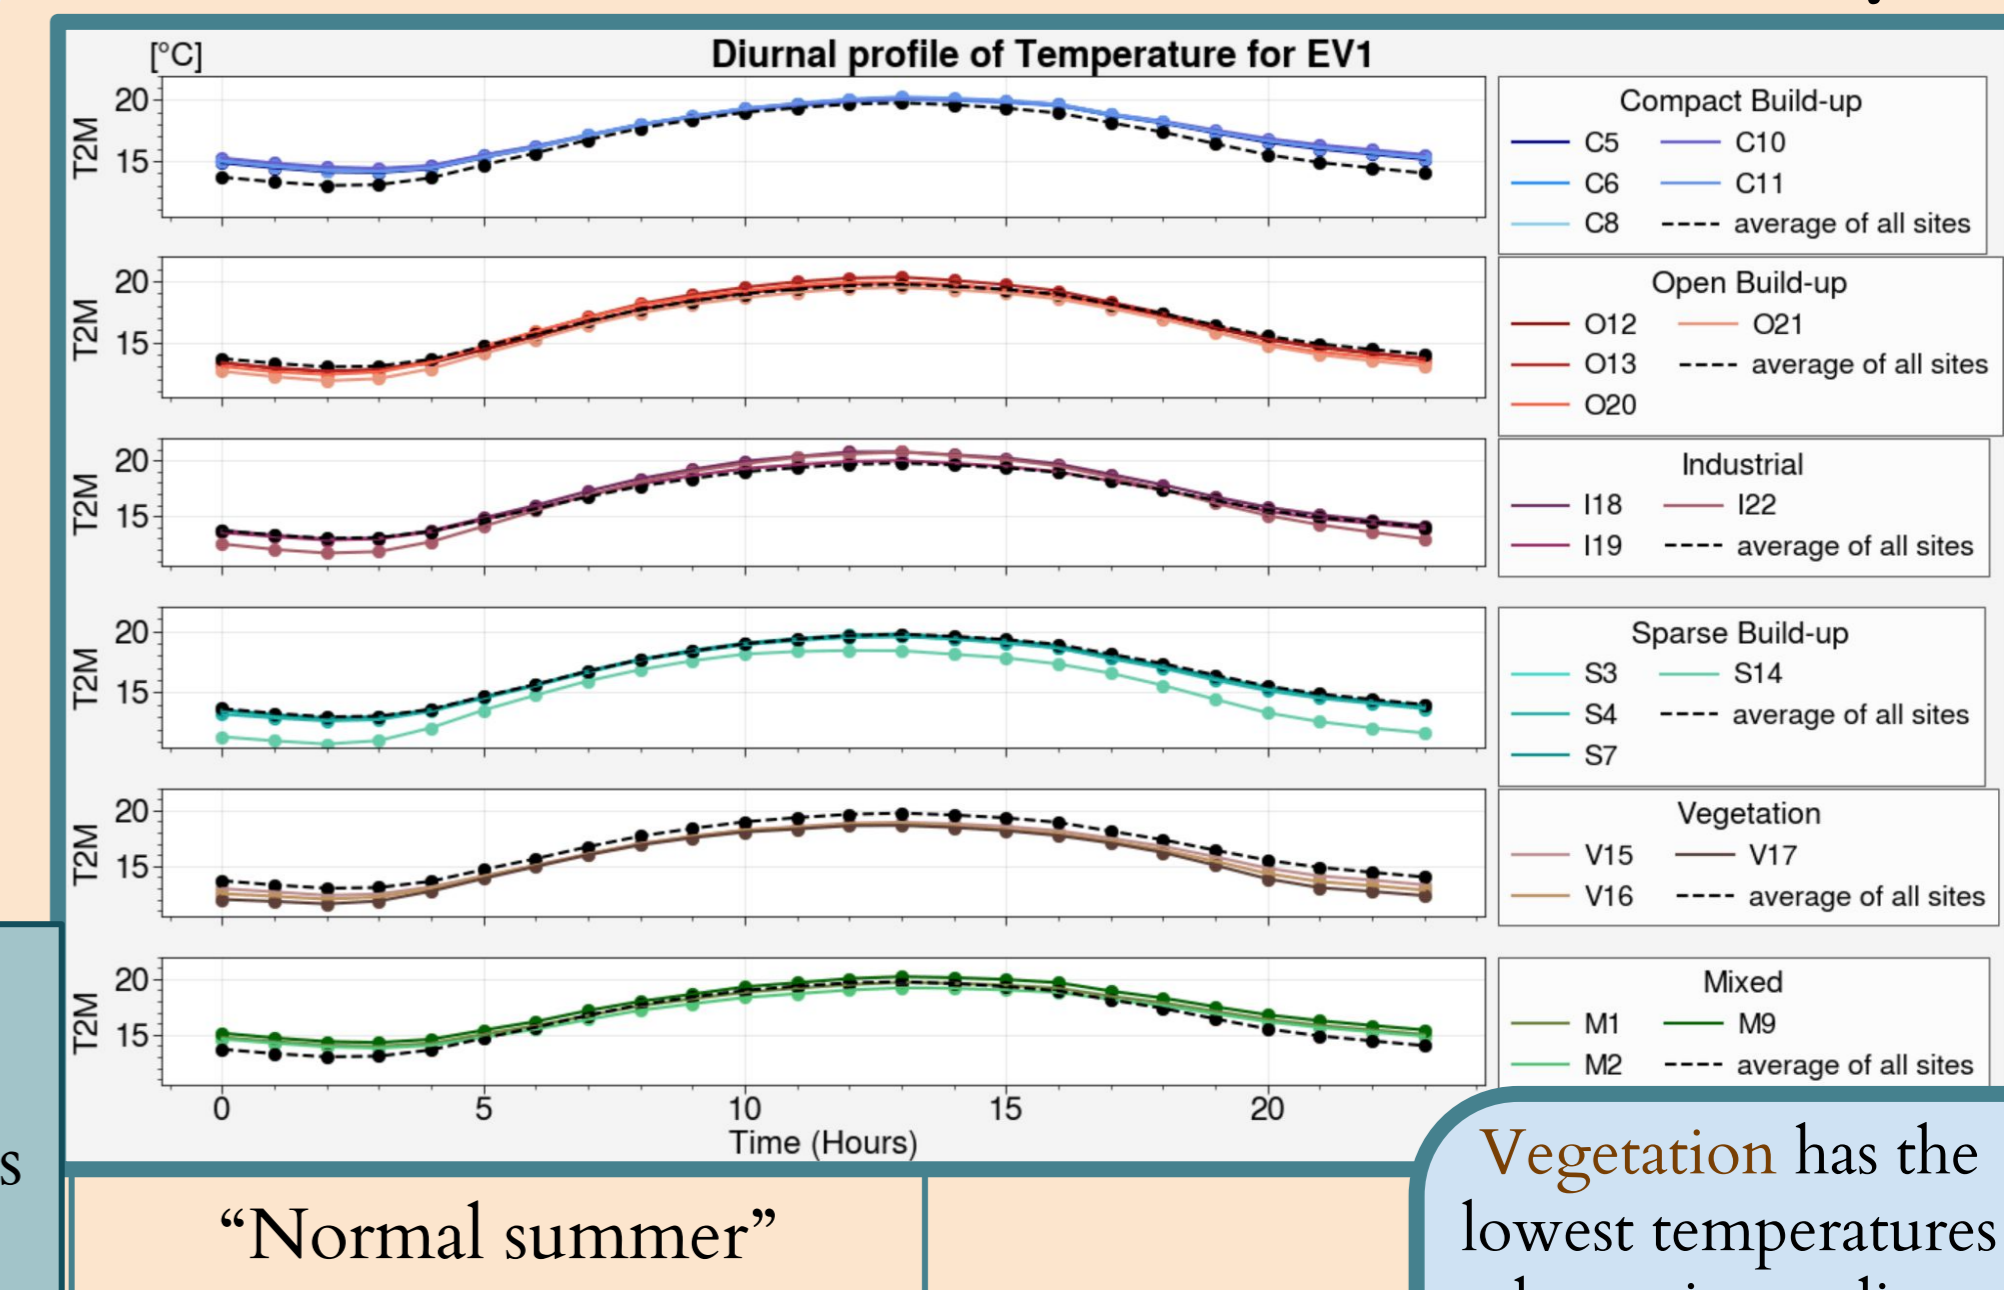

# Heat stress in Swedish Cities and the Role of Urban Planning

Helena Lindqvist  
helena.lindqvist98@hotmail.com

The thesis can be found here!

# What was found from the study?

See BOX 1 for LCZ-groups reference!

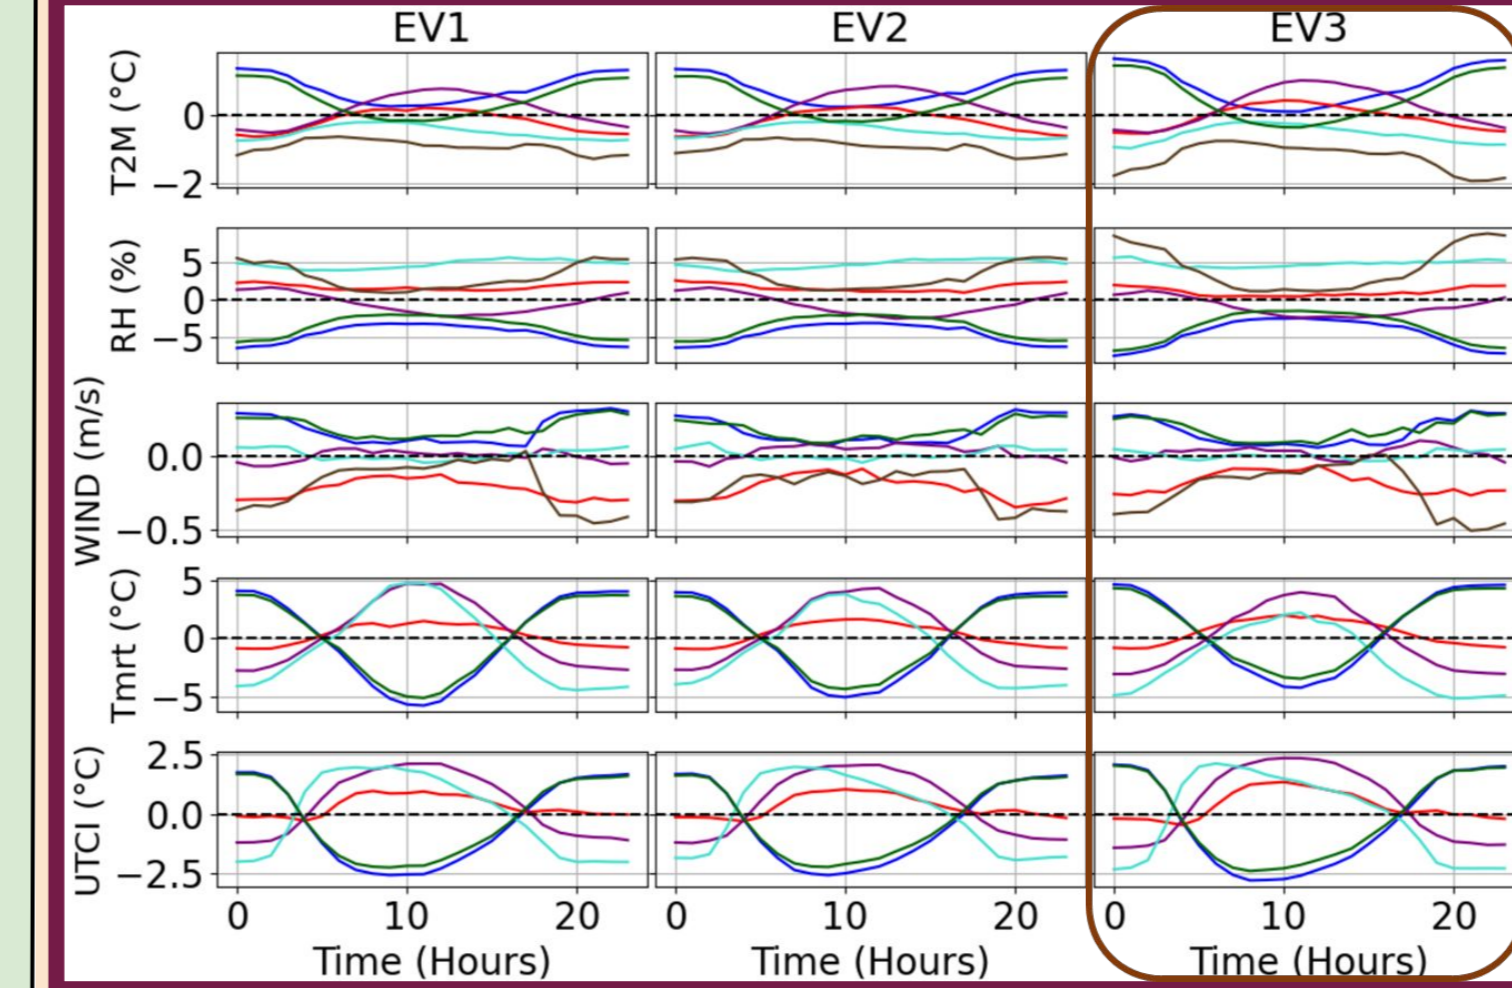

Vegetation has the lowest temperatures due to its cooling evaporative mechanism, and shading providing a mitigating effect. Compact Build-up provides shading during the day, decreasing the heat stress. It has the highest night temperatures due to the heat from the day being released.

## Research Questions:

Focusing on the Swedish city of Stockholm, this study investigates the following research questions:

1. To which degree have different urban planning typologies (defined according to the LCZ classification) contributed the most to reduce the heat stress in the city?
2. How is the relationship between the LCZs and heat stress affected by different climate conditions, including heatwave events?

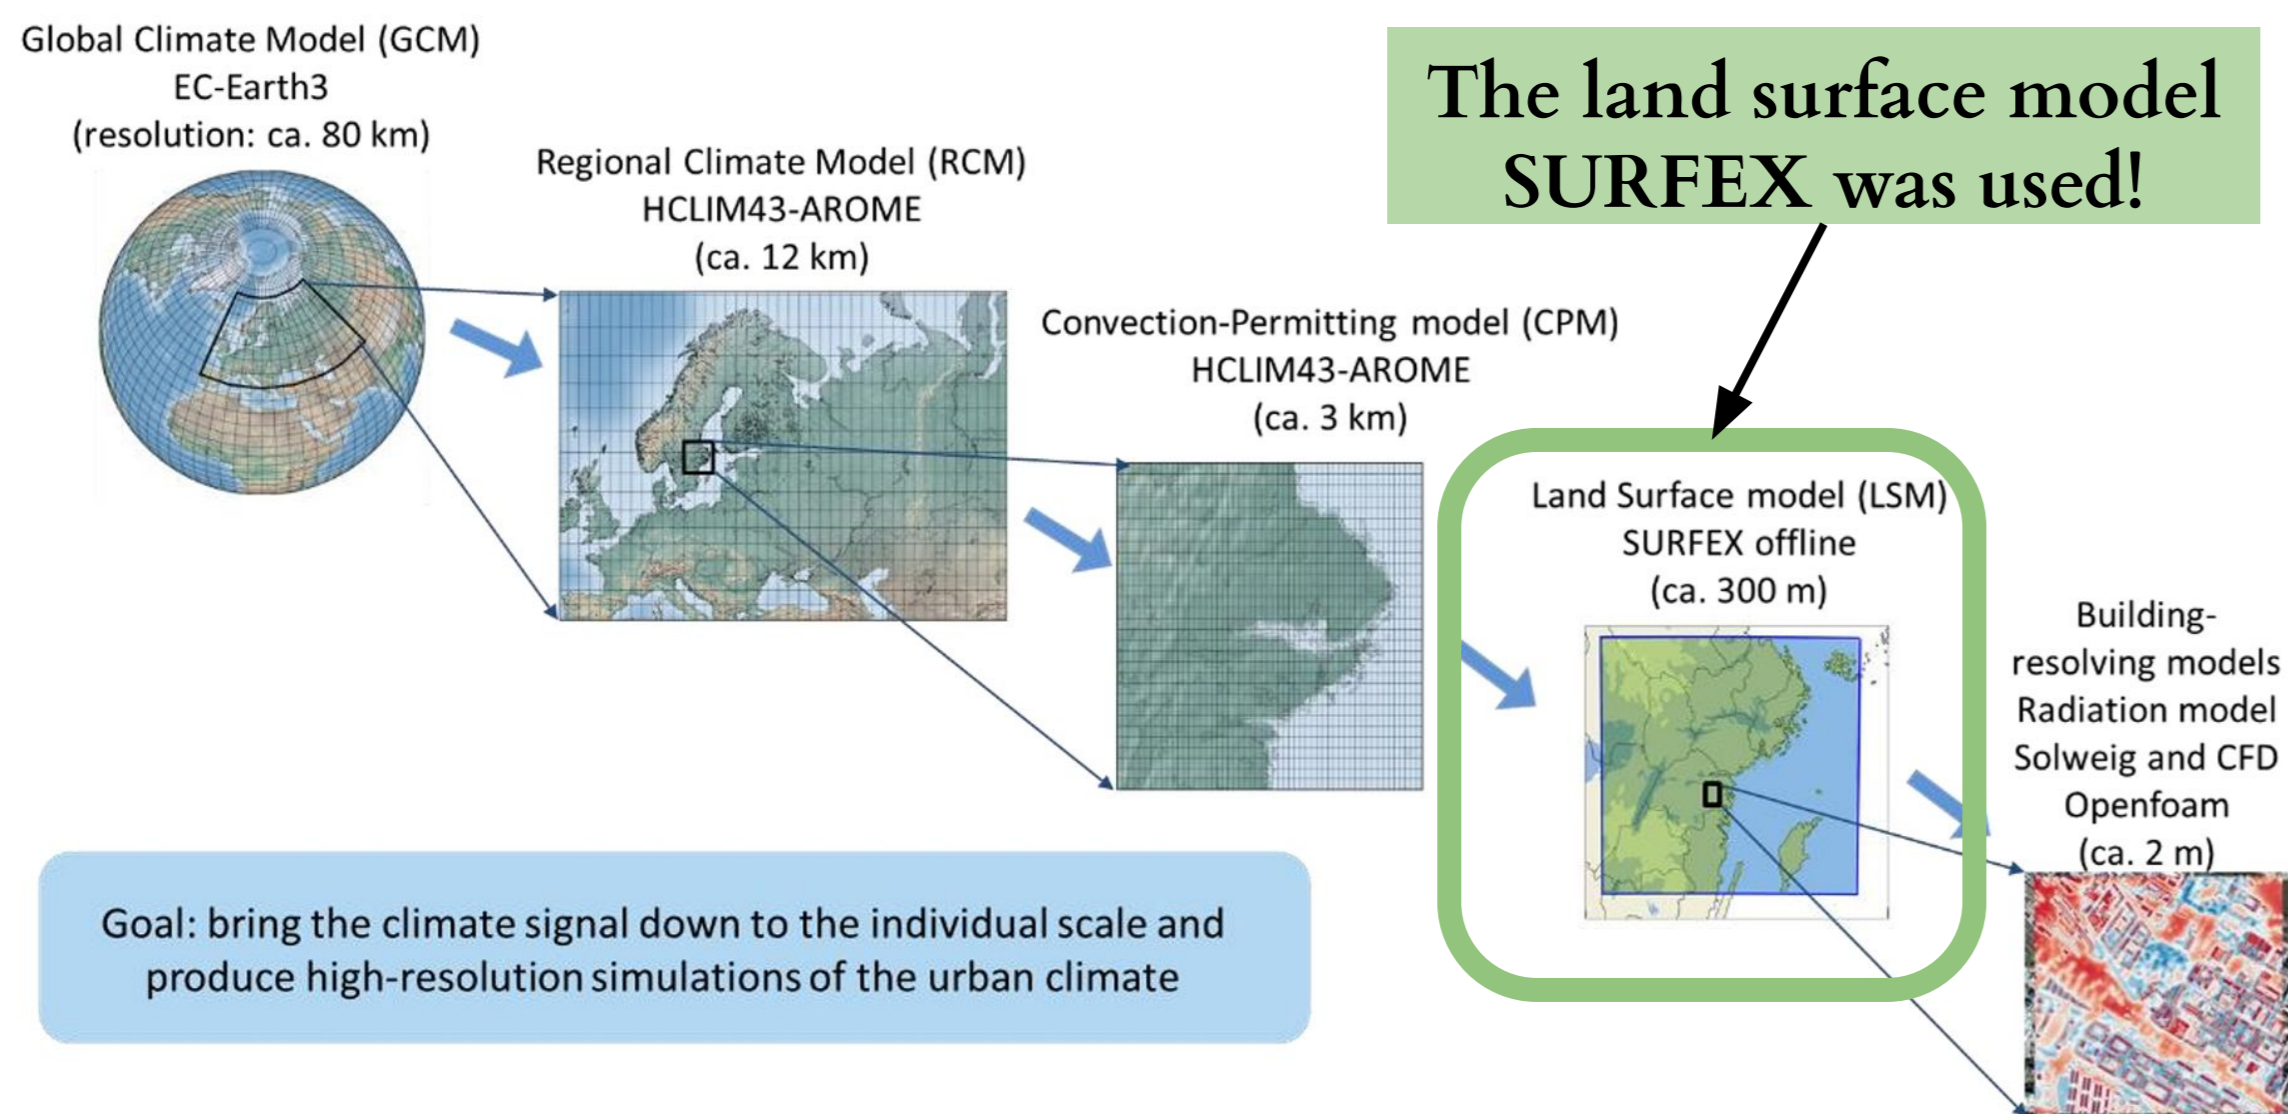

## Deviant Diurnal Profiles for EV1, EV2, and EV3

The largest deviations were found for Compact Build-up and Mixed during EV3. Studies have shown how UHI is intensified during more extreme conditions, which could be an explanation for this.

# Methodology

## Dynamical downscaling of the urban climate

The land surface model SURFEX was used!

Goal: bring the climate signal down to the individual scale and produce high-resolution simulations of the urban climate

## Five parameters were analysed:

1. Air temperature at 2m (°C)
2. Relative humidity at 2m (%)
3. Wind at 10m (m/s)
4. Mean Radiant Temperature (MRT, °C):  
"The result of radiation fluxes that the individual is affected by"
5. Universal Thermal Climate Index (UTCI, °C): A heat index that is formed by combining parameters 1-4. Its value represents how the individual perceives the heat with different consequences on the human body based on heat stress.

- G1, Compact Build-up: LCZ 1-3**  
**G2, Open Build-up: LCZ 4-6**  
**G3, Industrial: LCZ 8, 10**  
**G4, Sparse Build-up: LCZ 9**  
**G5, Vegetation: LCZ A**  
**G6, Mixed: LCZ 1, 9, G**

Can micro-climates within a city affect the heat stress and the thermal comfort of the individual to different extents? The **Local Climate Zone (LCZ) Classification** can be used to understand this!

## BOX 1

Built types	Non-built types
LCZ 1 - Compact high-rise	LCZ A - Dense trees
LCZ 2 - Compact midrise	LCZ B - Scattered trees
LCZ 3 - Compact low-rise	LCZ C - Bush, scrubs
LCZ 4 - Open high-rise	LCZ D - Low plants
LCZ 5 - Open midrise	LCZ E - Bare rock or paved
LCZ 6 - Open lowrise	LCZ F - Bare soil or sand
LCZ 7 - Lightweight low-rise	LCZ G - Water
LCZ 8 - Large low-rise	
LCZ 9 - Sparsely built	
LCZ 10 - Heavy industry	

## Local Climate Zone (LCZ) Classification

## Event-based approach

To understand how the LCZs are affected in different climate conditions, three representative summers (events, EV) are selected:

- ❖ The summer of 2017 - a normal Swedish summer (EV1)
- ❖ The summer of 2022 - a hot summer (EV2) → up to 2°C higher than the normal
- ❖ The summer of 2018 - an extreme hot summer (EV3) → up to 4°C higher than the normal

## Take home message

- Shading from vegetation and buildings had a mitigating effect during the day where buildings are densely constructed, while the latter contributed to a warming effect during the night.  
 - The heat stress is higher for densely built areas during extreme climate conditions, such as the summer of 2018.

In order to reduce the heat stress in cities, municipalities need to take the role of micro-climates into consideration in urban planning.
